Academic Productivity Series

## Annual CPS Test Trend Review, 1999

John Q. Easton<br>Todd Rosenkranz<br>Anthony S. Bryk<br>Brian A. Jacob<br>Stuart Luppescu<br>Melissa Roderick

adjustments, the overall systemwide scores were still up from 1997. This current data brief updates that effort to monitor IT BS achievement results in the C hicago Public Schools and introduces other relevant factors into the discussion as well. These two research data briefs mark the beginning of a series of annual reports from the C onsortium, anal yzing IT BS trends in theC PS.

## Part 1. Who Is Tested and Who Is Included in the Accountability System?

Chicago Public Schools administers the Iowa Tests of Basic Skills late in the spring each year in all elementary schools. All but a small portion of students in grades three through eight take the tests. ${ }^{1}$ H owever, not all students who take thetest are included in CPS's accountability system. Some who take the test are not counted in reports that are used to judge progress of the

Figure 1 ITBS Inclusion Rates

Note: See Table A for more detail, including grade 20.
school system over time, nor are they included in statistics used to determine whether schools are put on or taken off probation. Similarly, most of the students whose scores are excluded from the accountability system are not subject to thetest score requirements of thestudent promotion policy. The changing exclusion rates make it difficult to draw accurate judgments about school improvement and student progress in many schools, as well as across the system as a whole.
Although total enrollment in CPS elementary schools increased during the second half of the 1990s, the percent of students whose test scores are included in the annual report decreased. In 1992, 82.3 percent of students were included in the public reporting of IowaTests of Basic Skills
scores. In 1999, the most recent citywide test administration, the percent of studentsincluded was down to 73.9. The lowest inclusion rate occurs in thethird grade, whereal most onethird of students are not counted in the accountability system. ${ }^{2}$ Figure 1 displays the inclusion rates by grade for the years 1992 to 1999. (Table A, pages 12 amd 13, containsgreater detail, including the total enrollment in CPS's target accountability population, thenumber of studentstested and included, the number tested but excluded, and the number not tested for 1992 to 1999.) For the most part, the decline in inclusion rates isincremental each year, though therearerelatively large declines in inclusion among third graders in 1997 and among fourth graders in 1999.

These drops in inclusion are driven by two trends: changing demographics and administrative change in the testing policy. M ost important is the increasing number of students in bilingual education programs. T his group of children represents a growing portion of CPS enrollment and is projected to continueincreasing over the next several years.
CPS has changed its policy twice over the last three years on the exclusion of bilingual students from the accountability system. In 1997 and 1998, students were not counted in traditional test score reports until after they had completed three full years (beyond kindergarten) in a bilingual program. Therefore, most English Ianguage learners entered the accountability system for the first time in fourth grade. In 1999, fifth grade becamethepoint wheretest scores for large numbers of bilingual education students were included (after four years). As a result, the inclusion rate for fourth grade dropped. Concurrent with this 1999 change, CPS required bilingual education students to betested on the ITBS after their second year in the program, rather than their third year, thus increasing the number of students actually tested though not included.
A separatechange in testing practice occurred in 1997. Prior to that date, any bilingual students who were tested were included in test reporting, whether or not they were required to betested (that is, after three full years). In order to remove thisdisincentive, CPS allowed for students to be tested earlier and excluded from the public reporting system, so that they would not "count against" their school. The increased testing of bilingual students is responsiblefor a drop in inclusion among third graders in 1997.

Recent changes in special education policies have also contributed to increased numbers of students in grades three through eight, though few of the students responsible for the increase in enrollment are included in the test accountability system. In the past, a significant number of special education students were placed in "non-graded" classrooms and assigned a grade code of 20 in the student information system. As grade 20s, these students were almost never counted in the testing results, not only because of their disabilities, but also because administratively they were not enrolled in regular grades three though eight. O utside of these regular grades, the scores did not fit in the CPS reporting framework.

CPS has greatly reduced the number of students in "grade 20." In 1992, 6,180 students (in the appropriate age range for grades three through eight) were classified as grade 20. By 1999, only 773 were (see Table A). Although very few of these students are (or ever were) included in traditional test reporting, ${ }^{3}$ they arenow classified in regular grades and counted either as not tested or as tested but excluded.

Table B, page 14, provides further detail on the reasons why student scores were excluded from reporting for the past three years (the years for which data are most readily available). The multiple changes in inclusion patterns over the years reflect reasonable policy changes that conform to special education regulations and legal mandates. They are intended to expose students to the test earlier and to respond to the requirement for greater mainstreaming of special education students. N onetheless, they still complicate interpretations of the test score trends, particularly in the early grades.

## Part 2. Elementary School Test Score Trends in CPS

Test scores in CPS elementary schoolshave been rising for several years now. Several factors (in addition to the changing inclusion criteria described above) complicate interpretation of the rising test scores, however. Chief among these is the effect of the retention policy on the student composition of grades three through eight. Increasingly, the new promotion policy is changing what it means to be enrolled in a specific grade. Since fall 1997, for example, the third grade comprises first-timestudents as well assignificant numbers of second-timethird gradersstudents repeating the third grade because they did not reach a specified test score cutoff. In the 1999 school year, therewere even somestudents enrolled in thethird gradefor athird time. Prior to 1997, relatively few students were held back, so that the third grade was composed primarily of students enrolled as first-time third graders. Now we have increased numbers of ten and eleven year olds in third grade. Because of this shift in the gradelevel composition, simplecomparisons of scores over time can be misleading.

The retention policy not only affects test scores in grades three, six, and eight (those grades targeted by the promotion policy), it also affects scores in adjacent higher grades because these grades now have lower enrollments. M oreover, because weaker students are now held back, the scores in fourth, seventh, and ninth grades are inflated by this factor. Again, we are concerned about trying to ascertain the extent to which the increases are due to changes in which students are counted in each grade versus real improvements in school performance.

The first year after the new policy, it was relatively easy to adjust for these changes by removing the retained students from their retained grades and counting their scores with the grades they would have been in prior to the policy. But after two years, more grades and more students are affected by retentions. For example, in 1998 the fifth grade was not affected by changing retentions in the third and sixth grades. In 1999, however, the fifth grade is missing students who were retained in third grade in 1997. Instead of being in fifth gradein 1999, they werein thefourth grade. The simple techniques that we used to adjust scores in 1998 are no longer sufficient to deal with thegreater complicationsof gradeenrollments.
By reporting thetest scoretrends by agegroups rather than grade, we can keep the comparison group constant over time. In this study, we de fined age in such a way as to complement CPS age requirements for entry into school. For example, the nine year old group (usually third graders) consists of all students whose ninth birthday fell between September 1 and August 31 of a given academic year. ${ }^{4}$ For school year 1998-99, all students who celebrated their ninth birthday on any date between September 1, 1998 and August 31, 1999 are classified as nine year olds.
Thetest score trends by age are displayed in Figure 2. The outcome measure plotted on these graphs is the mean (average) grade equival ent, rather than any of the alternative statistics, such as percent at or above grade level, median percentile, or median grade equival ent. We argued in a 1998 C onsortium report that the mean is the most sensible single statistic to report, given that it is sensitive to the performance of all included students, un-

Ten Year Olds

Thirteen Year Olds

Note: See Tables C and D, pages 15 and 16, line "All", for more detail.
like other indicators that are mostly influenced by groups of studentsclustered in narrow scoreranges ${ }^{5}$

Because of changes in inclusion rules, we have made additional adjustments, reflected in Figure 2. To make test scores as comparable as possible over time, we added back in a group of students in 1999 who would have been included in 1997 and 1998. This adjustment had the greatest effect on ten year olds in 1999 when we added 3,800 students back in. On average, these students score lower than other ten year olds, so when they are added back into the total, they have the effect of bringing the average down. Because ten year olds (fourth graders) were most affected by this policy change, the adjustments make little difference among other age groups, though there is a notable difference for eleven year olds in reading and math.

We also subtracted a small group of students in 1995 and 1996. These arestudents who were included in those years, but would not havebeen had the 1997 and 1998 rules applied. Relatively few students are affected by this adjustment and the aggregate test scores change very little as a result.
O verall, CPS elementary school test scores continue to improve after the adjustments described above. Figure 2 indicates continuing, long-term improvement trends across all grades in math. Upward, positive trends in both reading and math are apparent among older students ( 13 and 14 year olds). In the last two years, reading improvement at ages 9,11 , and 12 appears to have slowed.

The achievement gap between minority and non-minority students has received a great deal of national attention and many strategies are being implemented to address this issue. ${ }^{6}$ T hus, we continuethat line of investigation in thisstudy
by disaggregating the trends shown in Figure 2 by student race/ethnicity (see Figure 3). Disaggregation allows us to examine the extent to which different racial/ethnic groups are participating in the upward trends in test scores. We found the following:

- In both reading and math, Asian and whitestudentsscoreconsistently higher than Latino and African-American students. Asian and white students tend to be above the national average grade leve; Latino and African-American students tend to be below grade level.
- Thetrends of African-American students and Latino students are relatively similar to each other over time in both reading and math, though Latino students score slightly higher in math than African-American students.
- The trends of white and Asian students are similar to each other in reading and math, but Asian students score significantly higher in math than white students.
- In general, African-American and Latino students' scores made slightly smaller improvements than white and Asian students in the period 1992 to 1999, though in more recent years, the improvements for these students have accelerated, especially for the twelve to fourteen year old students.
- We note that adjusting the 1999 test score average for the bilingual policy changes affects Latino, Asian, and white students' test scores, particularly ten year olds. In all cases, the adjustment lowers the average score.

Figure $3 \quad$ Average ITBS Results by Race/Ethnicity

Note: The bold-faced Grade Equivalent (GE) on the left axis indicates the national average GE for that grade level. See Tables $C$ and $D$, pages 15 and 16 , for more detail.

## Part 3. Trends in Learning Gains Over Time

Although the test score trends described in the previous section suggest general improvements in theCPS, the average achievement level is not the best indicator of school improvement systemwide. For a more careful look at system changes, we turn to an investigation of gains in students' test scores over time. As we argued in our 1998 study,' because gains measure the amount of learning that has taken place from one time point to another. By comparing changes in gains over time, we have our best information about changes in theoverall productivity of the CPS. Because gains are calculated by subtracting a previous year's score from the subsequent score, they also introduce a control for mobility into and out of the school system.

Simple comparisons of gain scores are, however, complicated by changes in the specific form of the ITBS administered from year to year. CPS has used four separateITBS forms since 1992: Form H in 1992, Form K in 1993 and 1995, Form L in 1994, 1996, and 1998, and Form M in 1997 and 1999. Aswehaveshown previously, this adds considerable variability to the data, making analysis of trends more difficult. Fortunately, there are two comparisons that are straightfor-

ward. Both the 1994 and the 1996 gains are computed from aK to $L$ form pattern, so they are directly comparable to each other. Similarly, the 1997 and the 1999 gains are computed from forms $L$ and $M$ and can be compared to each other.

Figure 4 documents consistently higher gains in all grades in 1996 than in 1994, indicating a broad-based improvement in academic productivity in CPS elementary schools in this period of time. Looking forward to more recent years, the 1999 gains declined slightly in comparison to the 1997 gains in all but third grade. This suggests thepossibility that gainsin productivity in CPS may have peaked, though they are higher now than they were earlier. For example, the average math gain for fifth graders in 1995 was 0.93 GEs. By 1999, this increased to 1.02 GEs . In short, the system is now operating at a higher level of productivity than five years earlier, although our evidence suggests that the gains may no longer be increasing. As a result, test scores should continue to increase over the next several years, though at a diminished rate, until wholegroups of children have experienced the improved productivity across grades three through eight. Subsequently, we would expect aggregated trends to flatten out, until there is a renewed surge in productivity improvement.

## Endnotes

${ }^{1}$ Students with severe disabilities and students who are in the process of learning English do not take the ITBS.
${ }^{2}$ These rates vary greatly from one school to another, so in some schools accountability measures are based on a much smaller portion of the total enrollment.
${ }^{3}$ CPS reports scores for students with disabilities separately as a result of a legal settlement.
${ }^{4}$ The required minimum age for entering kindergarten changed between 1987 and 1990. At the beginning of this period, students needed to reach their fifth birthday by D ecember 1 . The entering age increased by one month each year until 1990, when students needed to be five years old by September 1. We accounted for these transitions in our analyses.

This is the second in a series of research data briefs that present findings from the C onsortium on Chi cago School Research, departing from our regular, more comprehensive, in-depth studies. As the name suggests, this is a short report focusing on a single topic. The data brief is designed to provide new data on a particular issue, in a timely fashion. Because data briefs are not comprehensive studies, we limit our discussion of findings to summarizing the key results.

This data brief reflects the interpretations of the authors. Although the C onsortium's Steering Committee provided technical advice and reviewed an earlier version of this brief, no formal endorsement by these individuals, their organizations, or the full Consortium should be assumed.
